

ICT703 Programming

Module 4 Topic 1

Strings

Objectives

1. Access individual characters in a string
2. Retrieve a substring from a string
3. Search for a substring in a string
4. Use string methods to manipulate strings

Programming Concepts

Four control flow

- Sequence
- Iteration
- Selection
- Abstraction – methods/classes

Data

The Structure of Strings

- An integer can't be factored into more primitive parts
- A string is a **data structure**
 - Data structure: Consists of smaller pieces of data
 - String's length: Number of characters it contains (0+)
- The **len** function returns the string's length, which is the number of characters it contains

len("Hi there!")

9

len("")

0

Figure 4-1 Characters and their positions in a string

Functions, Operators and Methods

- There are many ways to manipulate strings in python
 - Functions
 - Operators
 - Methods
-

Python functions

- Some functions cannot be used with strings:

- `sum()`
- `abs()`

- Others can be used:

- `len()`
 - `min()`
 - `max()`
-

String operators

Operator	Description	Syntax	
+	Concatenates (joins) <i>string1</i> and <i>string2</i>	<code>string1 + string2</code>	<pre>a = "Tea " + "Leaf" print(a)</pre>
*	Repeats the string for as many times as specified by <i>x</i>	<code>string * x</code>	<pre>a = "Bee " * 3 print(a)</pre>
[]	Slice — Returns the character from the index provided at <i>x</i> .	<code>string[x]</code>	<pre>a = "Sea" print(a[1])</pre>
[:]	Range Slice — Returns the characters from the range provided at <i>x:y</i> .	<code>string[x:y]</code>	<pre>a = "Mushroom" print(a[4:8])</pre>
in	Membership — Returns True if <i>x</i> exists in the string. Can be multiple characters.	<code>x in string</code>	<pre>a = "Mushroom" print("m" in a) print("b" in a) print("shroo" in a)</pre>
not in	Membership — Returns True if <i>x</i> does <i>not</i> exist in the string. Can be multiple characters.	<code>x not in string</code>	<pre>a = "Mushroom" print("m" not in a) print("b" not in a) print("shroo" not in a)</pre>

The Subscript Operator

- The form of the **subscript operator** is:

<a string>[<an integer expression>]

- Example:

```
name = "Alan Turing"
```

```
name[0]
```

Examine the first character

```
'A'
```

```
name[3]
```

Examine the fourth character

```
'n'
```

```
name[len(name)]
```

Traceback (most recent call last):

File "<stdin>", line 1, in <module>

IndexError: string index out of range

```
name[len(name) - 1]
```

Examine the last character

```
'g'
```

```
name[-1]
```

Shorthand for the last character

```
'g'
```

```
name[-2]
```

Shorthand for next to last character

```
'n'
```

The Subscript Operator

- Subscript operator is useful when you want to use the positions as well as the characters in a string
 - Use a count-controlled loop

```
data = "Hi there! "
```

```
for index in range(len(data)):
    print(index, data[index])
```

```
0 H
1 i
2
3 t
4 h
5 e
6 r
7 e
8 !
```

Slicing for Substrings

- Python's subscript operator can be used to obtain a substring through a process called **slicing**
 - Place a colon (:) in the subscript; an integer value can appear on either side of the colon

<code>name = "myfile.txt"</code>	<code># The entire string</code>
<code>name[0:]</code>	
<code>'myfile.txt'</code>	
<code>name[0:1]</code>	<code># The first character</code>
<code>'m'</code>	
<code>name[0:2]</code>	<code># The first two characters</code>
<code>'my'</code>	
<code>name[:len(name)]</code>	<code># The entire string</code>
<code>'myfile.txt'</code>	
<code>name[-3:]</code>	<code># The last three characters</code>
<code>'txt'</code>	
<code>name[2:6]</code>	<code># Drill to extract 'file'</code>
<code>'file'</code>	

Testing for a Substring with the in Operator

- When used with strings, the left operand of **in** is a target substring and the right operand is the string to be searched
 - Returns **True** if target string is somewhere in search string, or **False** otherwise
- This code segment traverses a list of filenames and prints just the filenames that have a .txt extension:

```
fileList = ["myfile.txt", "myprogram.exe", "yourfile.txt"]
for fileName in fileList:
    if ".txt" in fileName:
        print(fileName)
```

```
myfile.txt
yourfile.txt
```

String methods

- To further manipulate strings, python has in-built string methods
 - All string methods return new values.
 - They do not change the original string.
-

String Methods

- A method behaves like a function, but has a slightly different syntax
 - A method is always called with a given data value called an **object**
<an object>.<method name>(<argument-1>, ..., <argument-n>)
 - Methods can expect arguments and return values
 - A method knows about the internal state of the object with which it is called
 - In Python, all data values are objects
-

String methods

<code>capitalize()</code>	Converts the first character to upper case
<code>casefold()</code>	Converts string into lower case
<code>center()</code>	Returns a centered string
<code>count()</code>	Returns the number of times a specified value occurs in a string
<code>encode()</code>	Returns an encoded version of the string
<code>endswith()</code>	Returns true if the string ends with the specified value
<code>expandtabs()</code>	Sets the tab size of the string
<code>find()</code>	Searches the string for a specified value and returns the position of where it was found
<code>format()</code>	Formats specified values in a string
<code>isupper()</code>	Returns True if all characters in the string are upper case
<code>join()</code>	Joins the elements of an iterable to the end of the string
<code>ljust()</code>	Returns a left justified version of the string
<code>lower()</code>	Converts a string into lower case
<code>lstrip()</code>	Returns a left trim version of the string
<code>maketrans()</code>	Returns a translation table to be used in translations
<code>partition()</code>	Returns a tuple where the string is parted into three parts
<code>replace()</code>	Returns a string where a specified value is replaced with a specified value
<code>rfind()</code>	Searches the string for a specified value and returns the last position of where it was found
<code>rindex()</code>	Searches the string for a specified value and returns the last position of where it was found
<code>rjust()</code>	Returns a right justified version of the string
<code>rpartition()</code>	Returns a tuple where the string is parted into three parts

<code>index()</code>	Searches the string for a specified value and returns the position of where it was found
<code>isalnum()</code>	Returns True if all characters in the string are alphanumeric
<code>isalpha()</code>	Returns True if all characters in the string are in the alphabet
<code>isdecimal()</code>	Returns True if all characters in the string are decimals
<code>isdigit()</code>	Returns True if all characters in the string are digits
<code>isidentifier()</code>	Returns True if the string is an identifier
<code>islower()</code>	Returns True if all characters in the string are lower case
<code>isnumeric()</code>	Returns True if all characters in the string are numeric
<code>isprintable()</code>	Returns True if all characters in the string are printable
<code>isspace()</code>	Returns True if all characters in the string are whitespaces
<code>istitle()</code>	Returns True if the string follows the rules of a title
<code>rsplit()</code>	Splits the string at the specified separator, and returns a list
<code>rstrip()</code>	Returns a right trim version of the string
<code>split()</code>	Splits the string at the specified separator, and returns a list
<code>splitlines()</code>	Splits the string at line breaks and returns a list
<code>startswith()</code>	Returns true if the string starts with the specified value
<code>strip()</code>	Returns a trimmed version of the string
<code>swapcase()</code>	Swaps cases, lower case becomes upper case and vice versa
<code>title()</code>	Converts the first character of each word to upper case
<code>translate()</code>	Returns a translated string
<code>upper()</code>	Converts a string into upper case
<code>zfill()</code>	Fills the string with a specified number of 0 values at the beginning

Commonly used methods

Method	True if
<code>str.center(width)</code>	Returns a copy of <code>str</code> centered within the given number of columns.
<code>str.count(sub [, start [, end]])</code>	Returns the number of non-overlapping occurrences of substring <code>sub</code> in <code>str</code> . Optional arguments <code>start</code> and <code>end</code> are interpreted as in slice notation.
<code>str.join(sequence)</code>	Returns a string that is the concatenation of the strings in the sequence. The separator between elements is <code>str</code> .
<code>str.lower()</code>	Returns a copy of <code>str</code> converted to lowercase.
<code>str.upper()</code>	Returns a copy of <code>str</code> converted to uppercase.
<code>str.split([sep])</code>	Returns a list of the words in <code>str</code> , using <code>sep</code> as the delimiter string. If <code>sep</code> is not specified, any whitespace string is a separator.
<code>str.strip([aString])</code>	Returns a copy of <code>str</code> with leading and trailing whitespace (tabs, spaces, newlines) removed. If <code>aString</code> is given, remove characters in <code>aString</code> instead.

Let's look at some of the Boolean methods

Method	True if
<code>str.isalnum()</code>	String consists of only alphanumeric characters (no symbols)
<code>str.isalpha()</code>	String consists of only alphabetic characters (no symbols)
<code>str.islower()</code>	String's alphabetic characters are all lower case
<code>str.isnumeric()</code>	String consists of only numeric characters
<code>str.isspace()</code>	String consists of only whitespace characters
<code>str.istitle()</code>	String is in title case
<code>str.isupper()</code>	String's alphabetic characters are all upper case

String Methods – split()

- Use split to count the words in a single sentence easy

```
sentence = input("Enter a sentence: ")
```

```
listOfWords = sentence.split()
```

```
print("There are", len(listOfWords), "words. ")
```

```
sum = 0
```

```
for word in listOfWords:
```

```
    sum += len(word)
```

```
print("The average word length is", sum / len(listOfWords))
```
